

Self-reported levels of Depression, Anxiety, and Stress in medical students during the first 6 months of medical school

A case study at the Medical College of
Wisconsin's Regional Campuses prior to and
during the COVID-19 pandemic

Jeffery Fritz, Ph.D.

Craig Hanke, Ph.D.

Erin Gruber

Background

- Survey all Regional Campus Medical Students - 2019-2020 pre-COVID
 - Survey distributed in August, November and February – avoided summative exam periods
 - 45 total, 90% survey return rate at both campuses
 - Survey collection in 2020-2021 influenced by COVID pandemic - return rates only comparable for August and February data sets
 - As such bulk of discussion will only focus on 2019-2020 data except for slides comparing COVID data set to that collected prior to COVID pandemic
- Survey included
 - Self report level of Depression, Anxiety or Stress
 - DASS 21 survey (21 questions) to assess the same
 - Unique non-identifiable linker to view longitudinal progression
- Survey is not clinically diagnostic for Depression, Anxiety or Stress
- Purpose – better understand regional campus student adjustment to medical school

Depression - Population

Comparing Self Assessed to DASS 21

Anxiety - Population

Comparing Self Assessed to DASS 21

Stress - Population

Comparing Self Assessed to DASS 21

Conclusion #1 (population data)

- Over the first 6 months of medical school at the regional campuses:
 - Depression levels across the student population appear low over the first 6 month of medical school (in general)
 - Anxiety and Stress level range from low to extremely severe with levels peaking in November in the mild to moderate range
 - Student self-reported higher levels of depression, anxiety and stress than those levels measured using the DASS 21 instrument

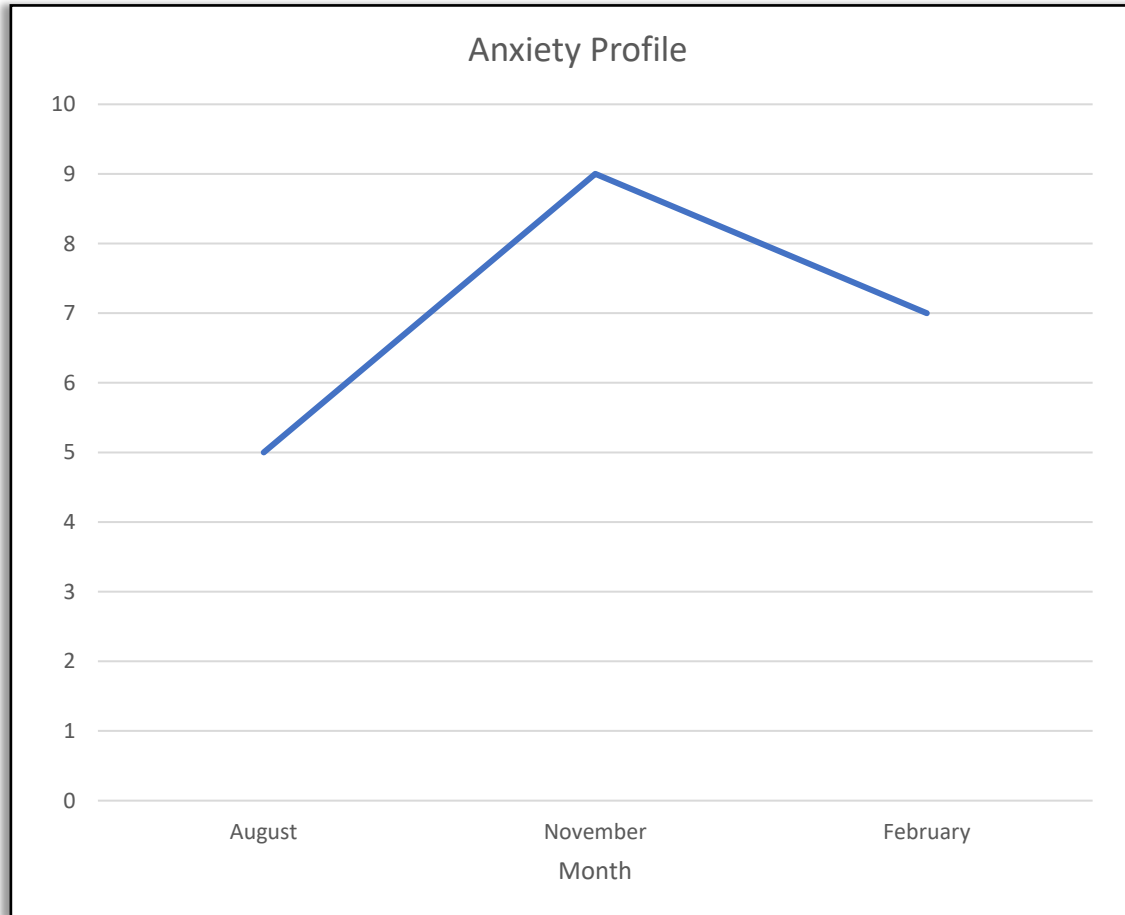

Profile Analysis - Depression

All scores in the normal/low range

4% data did not fit any profile

Profile Analysis - Anxiety

- Single profile – 73%
 - 27% did not fit any profile
- Scores ranged across mild/moderate to severe with peak always in November

Profile Analysis - Stress

- Scores ranged across mild/moderate to severe
- 15% of data did not fit either profile

Profile Analysis Conclusions

- Not everyone experiences depression, anxiety and stress the same
- Profiles suggest shared experiences with levels of anxiety and stress peaking in November compared to August or February
 - Causes?
 - Seasonal
 - Timing of Survey
 - Normalization of the medical school experience
 - Others

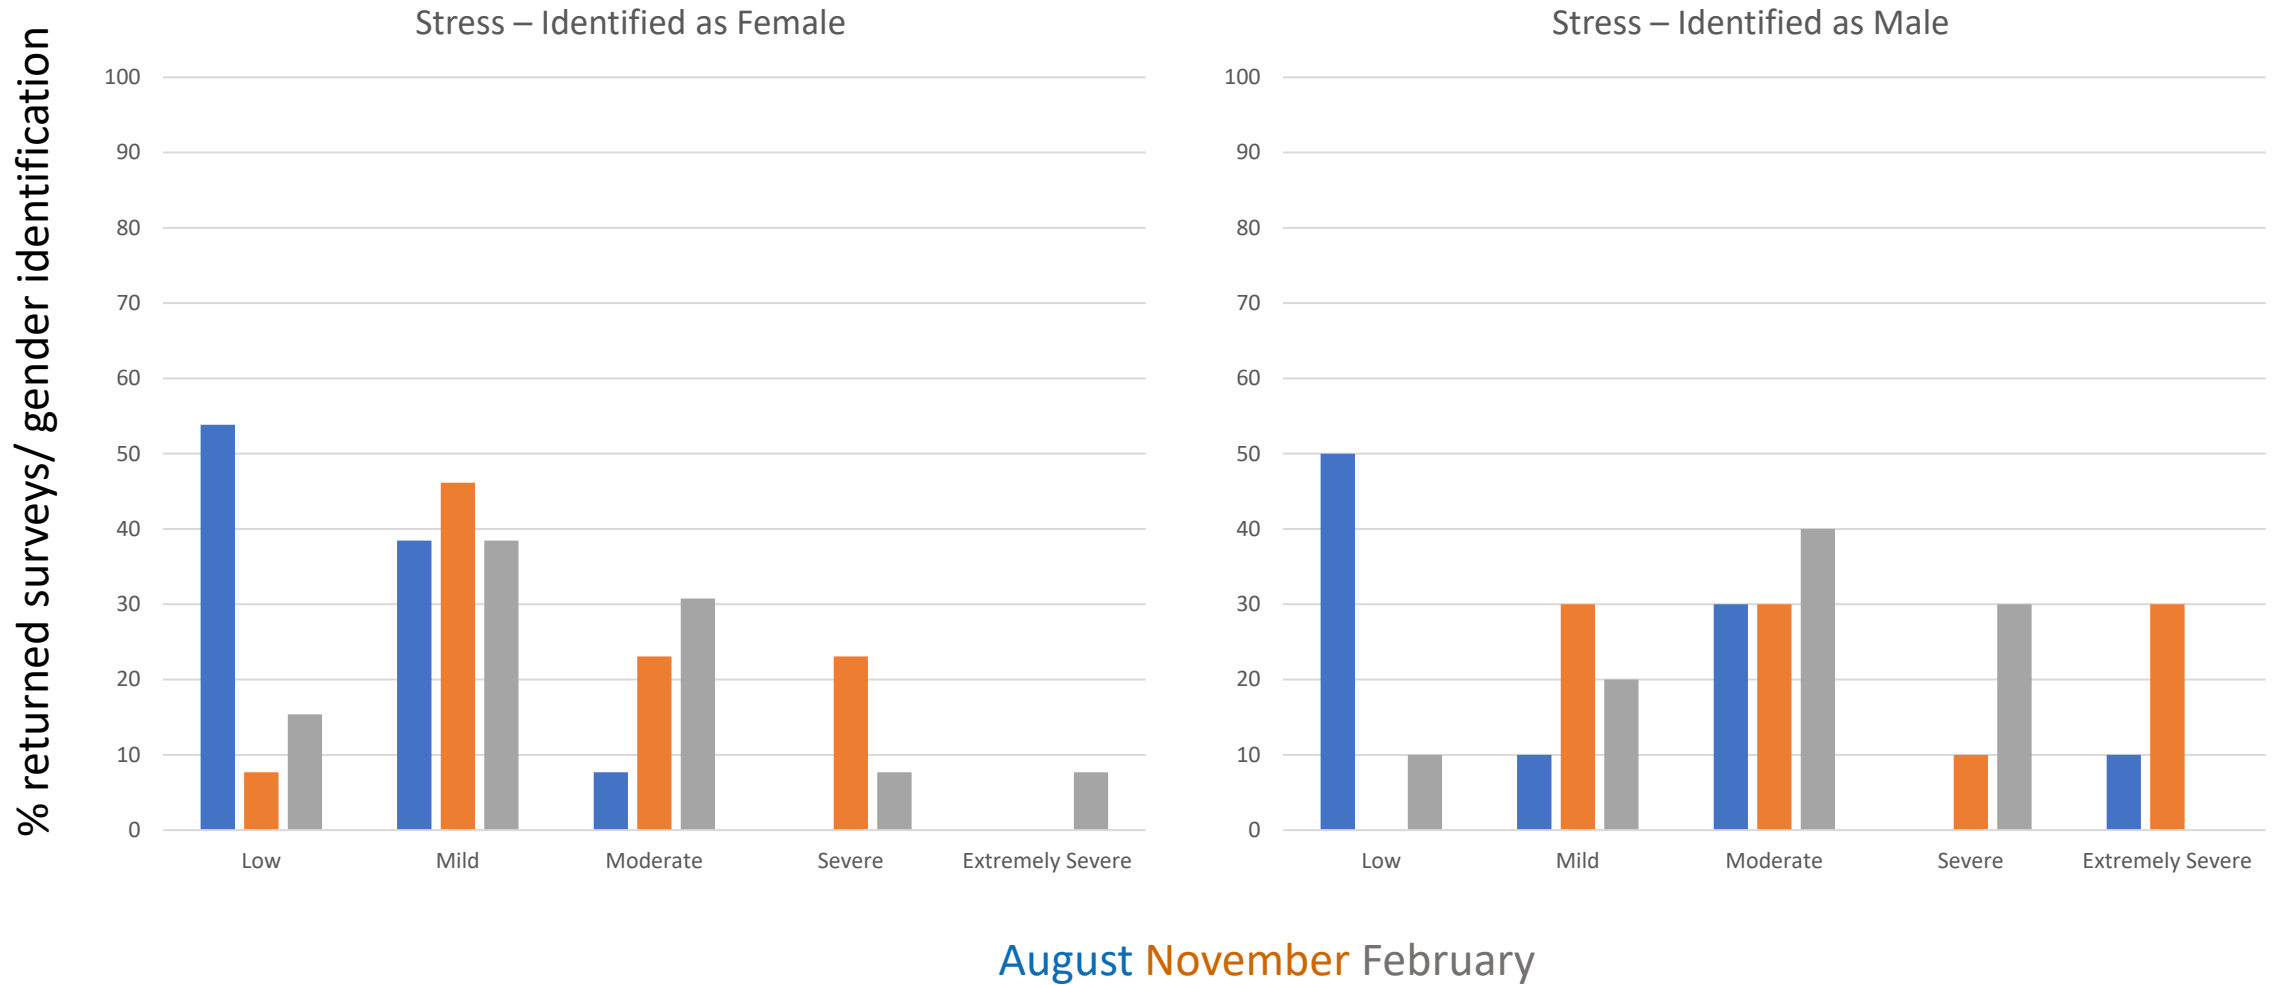

Gender Differences? (Depression)

Gender Differences? (Anxiety)

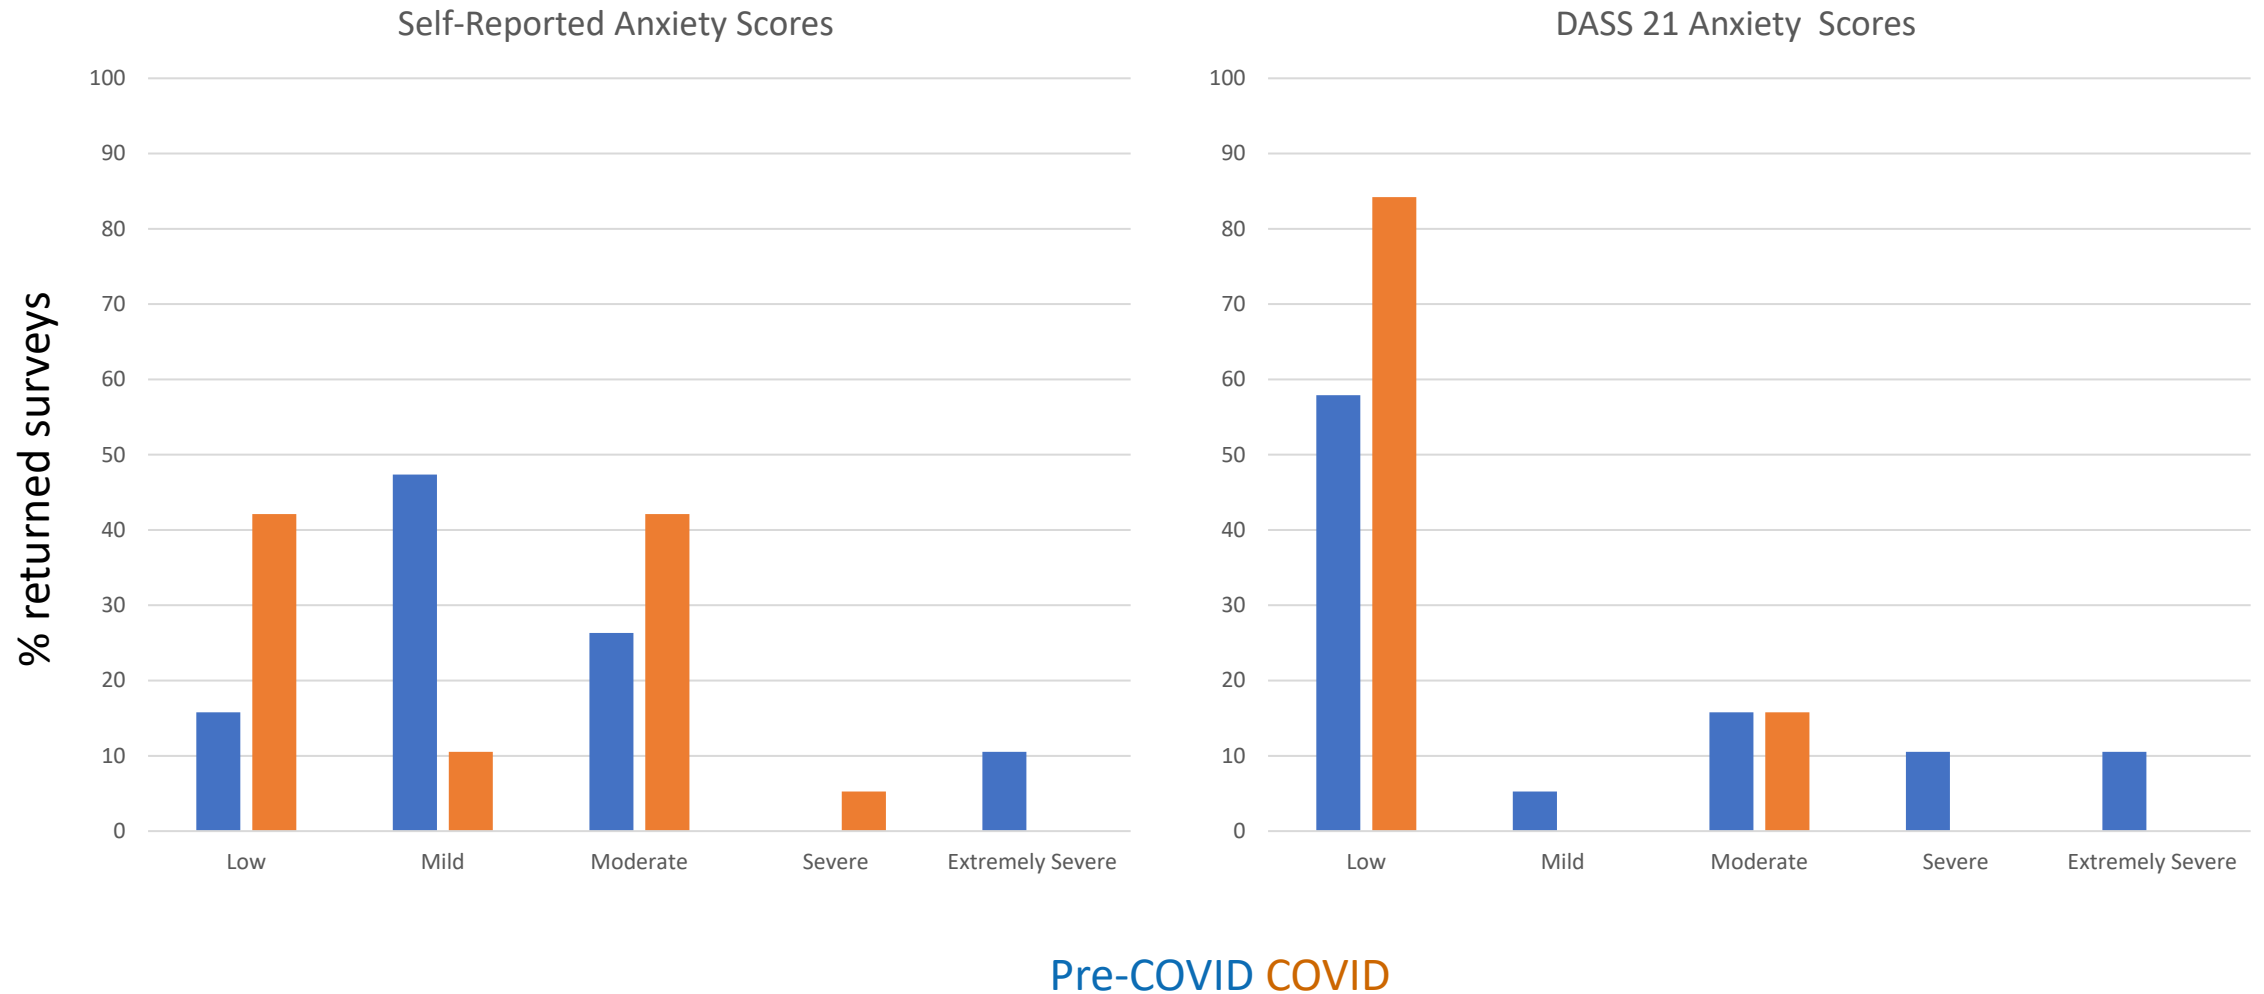

Gender Differences? (Stress)

Depression Pre-COVID and COVID - August Data

Anxiety Pre-COVID and COVID - August Data

Stress Pre-COVID and COVID - August Data

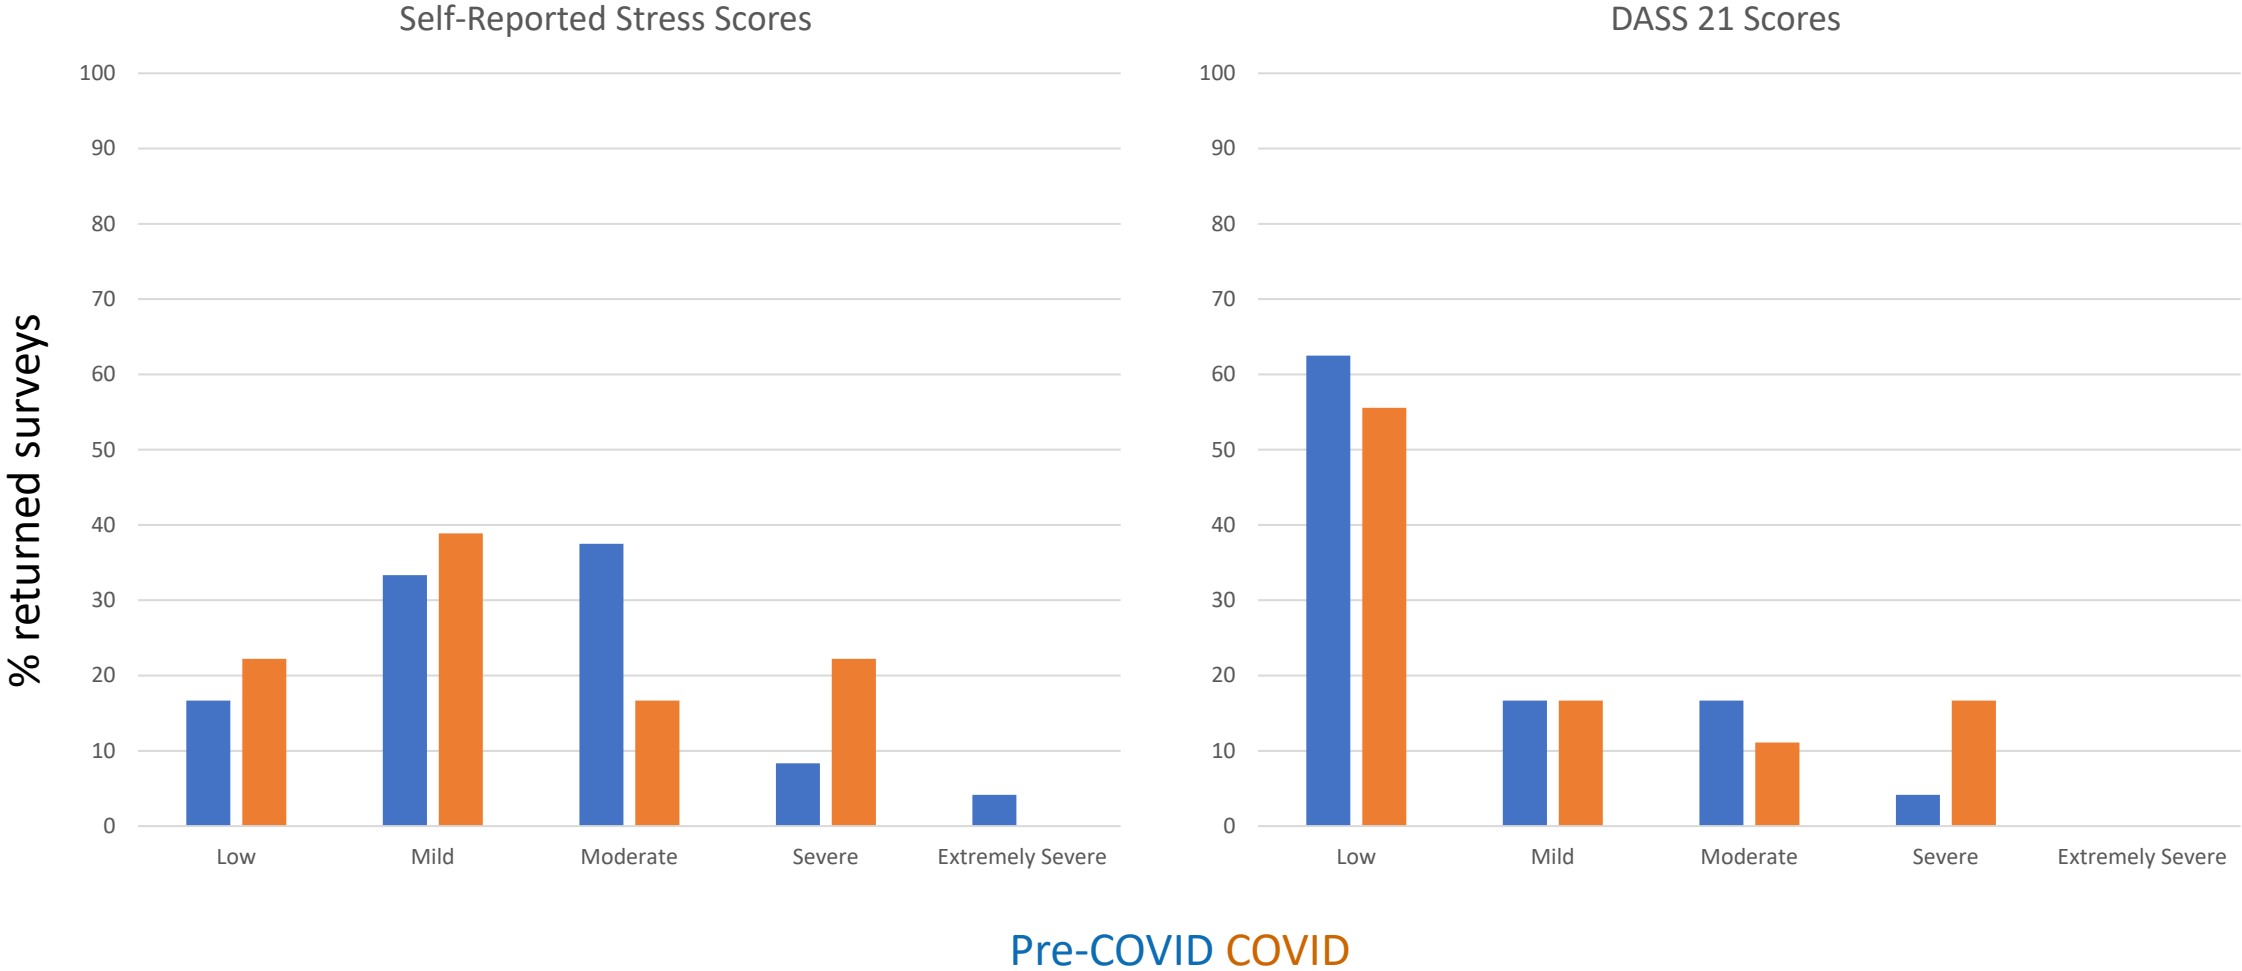

Depression Pre-COVID and COVID - February Data

Anxiety Pre-COVID and COVID - February Data

Anxiety Pre-COVID and COVID - February Data

Final Conclusions – Gender/COVID

- Male identifying students may have shown slighter higher levels of depression, anxiety and stress compared to female identifying students
- Levels of depression, anxiety and stress did not appear different in comparable pre-COVID and COVID datasets for the months of August and February.
